

# Cryptography and Network Security

Third Edition

by William Stallings

Lecture slides by Lawrie Brown

# Chapter 9 – Public Key Cryptography and RSA

*Every Egyptian received two names, which were known respectively as the true name and the good name, or the great name and the little name; and while the good or little name was made public, the true or great name appears to have been carefully concealed.*

**—The Golden Bough, Sir James George Frazer**

# Private-Key Cryptography

- traditional **private/secret/single key** cryptography uses **one** key
- shared by both sender and receiver
- if this key is disclosed communications are compromised
- also is **symmetric**, parties are equal
- hence does not protect sender from receiver forging a message & claiming is sent by sender

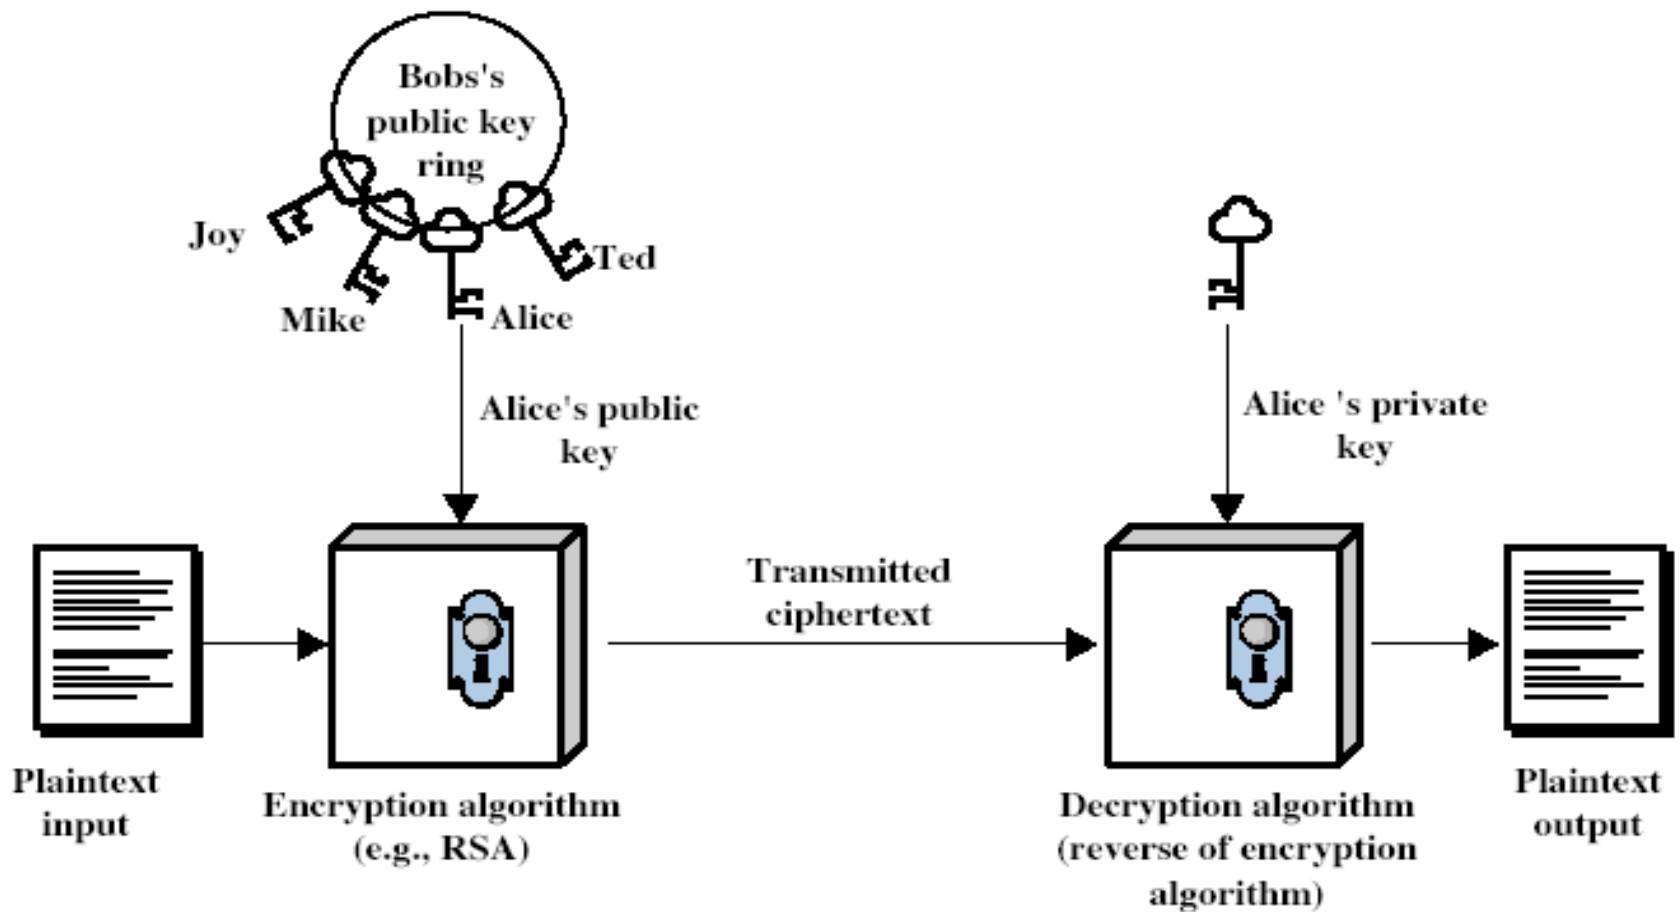

# Public-Key Cryptography

- probably most significant advance in the 3000 year history of cryptography
- uses **two** keys – a public & a private key
- **asymmetric** since parties are **not** equal
- uses clever application of number theoretic concepts to function
- complements **rather than** replaces private key crypto

# Public-Key Cryptography

- **public-key/two-key/asymmetric** cryptography involves the use of **two** keys:
  - a **public-key**, which may be known by anybody, and can be used to **encrypt messages**, and **verify signatures**
  - a **private-key**, known only to the recipient, used to **decrypt messages**, and **sign** (create) **signatures**
- is **asymmetric** because
  - those who encrypt messages or verify signatures **cannot** decrypt messages or create signatures

# Public-Key Cryptography

# Why Public-Key Cryptography?

- developed to address two key issues:
  - **key distribution** – how to have secure communications in general without having to trust a KDC with your key
  - **digital signatures** – how to verify a message comes intact from the claimed sender
- public invention due to Whitfield Diffie & Martin Hellman at Stanford Uni in 1976
  - known earlier in classified community

# Public-Key Characteristics

- Public-Key algorithms rely on two keys with the characteristics that it is:
  - computationally infeasible to find decryption key knowing only algorithm & encryption key
  - computationally easy to en/decrypt messages when the relevant (en/decrypt) key is known
  - either of the two related keys can be used for encryption, with the other used for decryption (in some schemes)

# Public-Key Cryptosystems

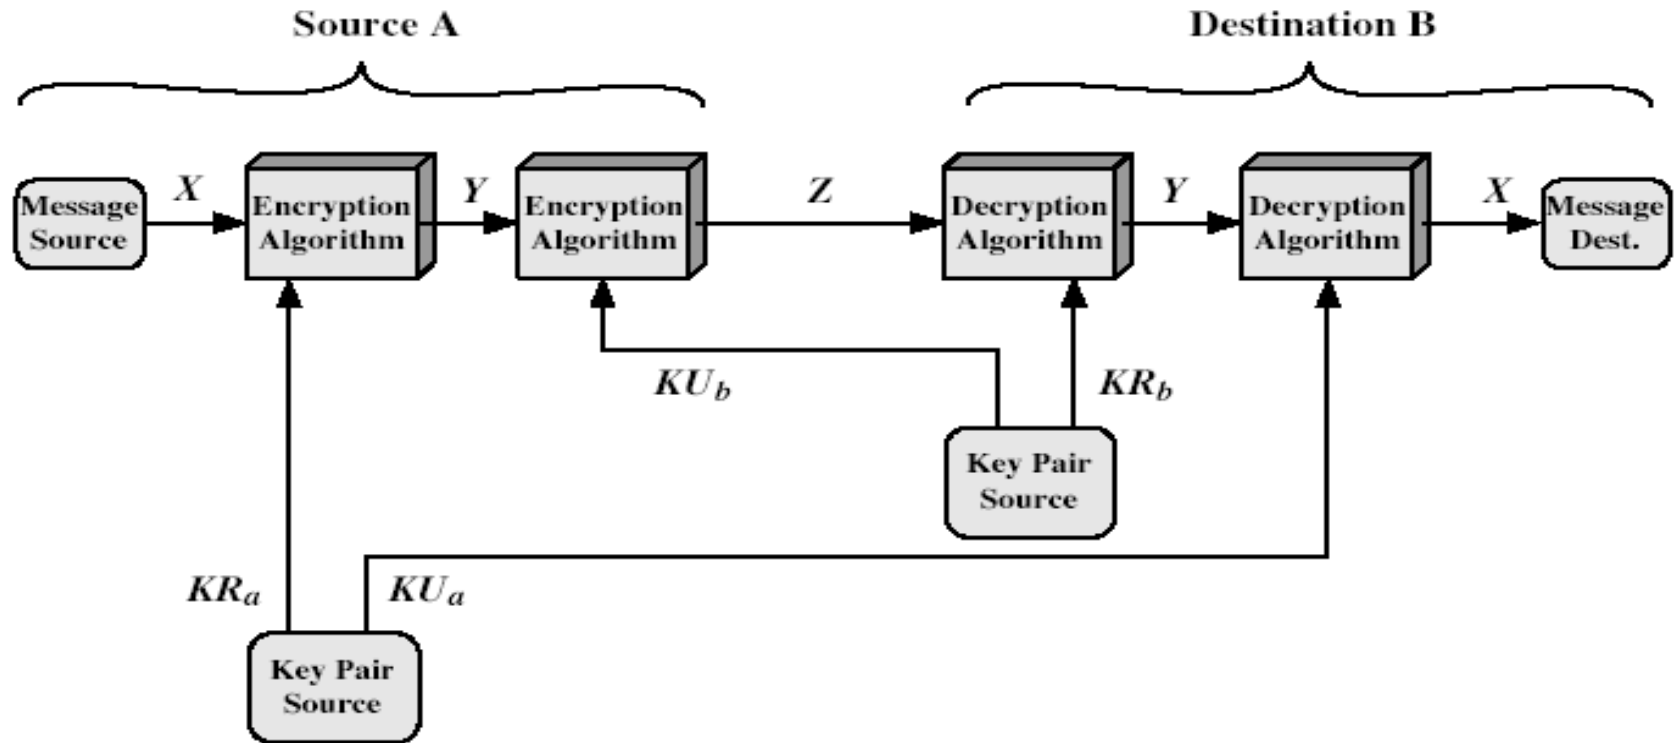

Figure 9.4 Public-Key Cryptosystem: Secrecy and Authentication

# Public-Key Applications

- can classify uses into 3 categories:
  - **encryption/decryption** (provide secrecy)
  - **digital signatures** (provide authentication)
  - **key exchange** (of session keys)
- some algorithms are suitable for all uses, others are specific to one

# Security of Public Key Schemes

- like private key schemes brute force **exhaustive search** attack is always theoretically possible
- but keys used are too large (>512bits)
- security relies on a **large enough** difference in difficulty between **easy** (en/decrypt) and **hard** (cryptanalyse) problems
- more generally the **hard** problem is known, its just made too hard to do in practise
- requires the use of **very large numbers**
- hence is **slow** compared to private key schemes

# RSA

- by Rivest, Shamir & Adleman of MIT in 1977
- best known & widely used public-key scheme
- based on exponentiation in a finite (Galois) field over integers modulo a prime
  - nb. exponentiation takes  $O((\log n)^3)$  operations (easy)
- uses large integers (eg. 1024 bits)
- security due to cost of factoring large numbers
  - nb. factorization takes  $O(e^{\log n \log \log n})$  operations (hard)

# RSA Key Setup

- each user generates a public/private key pair by:
- selecting two large primes at random -  $p, q$
- computing their system modulus  $N=p \cdot q$ 
  - note  $\phi(N) = (p-1)(q-1)$
- selecting at random the encryption key  $e$ 
  - where  $1 < e < \phi(N)$ ,  $\gcd(e, \phi(N)) = 1$
- solve following equation to find decryption key  $d$ 
  - $e \cdot d = 1 \pmod{\phi(N)}$  and  $0 \leq d \leq N$
- publish their public encryption key:  $KU=\{e, N\}$
- keep secret private decryption key:  $KR=\{d, p, q\}$

# RSA Use

- to encrypt a message  $M$  the sender:
  - obtains **public key** of recipient  $KU = \{e, N\}$
  - computes:  $C = M^e \bmod N$ , where  $0 \leq M < N$
- to decrypt the ciphertext  $C$  the owner:
  - uses their private key  $KR = \{d, p, q\}$
  - computes:  $M = C^d \bmod N$
- note that the message  $M$  must be smaller than the modulus  $N$  (block if needed)

# Why RSA Works

- because of Euler's Theorem:
- $a^{\phi(N)} \bmod N = 1$ 
  - where  $\gcd(a, N) = 1$
- in RSA have:
  - $N = p \cdot q$
  - $\phi(N) = (p-1)(q-1)$
  - carefully chosen  $e$  &  $d$  to be inverses  $\bmod \phi(N)$
  - hence  $e \cdot d = 1 + k \cdot \phi(N)$  for some  $k$
- hence :
$$C^d = (M^e)^d = M^{1+k \cdot \phi(N)} = M^1 \cdot (M^{\phi(N)})^k = M^1 \cdot (1)^k = M^1 = M \bmod N$$

# RSA Example

1. Select primes:  $p=17$  &  $q=11$
2. Compute  $n = pq = 17 \times 11 = 187$
3. Compute  $\phi(n) = (p-1)(q-1) = 16 \times 10 = 160$
4. Select  $e$  :  $\gcd(e, 160) = 1$ ; **choose**  $e=7$
5. **Determine**  $d$ :  $de=1 \pmod{160}$  **and**  $d < 160$   
**Value is**  $d=23$  **since**  $23 \times 7 = 161 = 10 \times 160 + 1$
6. **Publish public key**  $KU = \{7, 187\}$
7. **Keep secret private key**  $KR = \{23, 17, 11\}$

# RSA Example cont

- sample RSA encryption/decryption is:
- given message  $M = 88$  (nb.  $88 < 187$ )

- encryption:

$$C = 88^7 \bmod 187 = 11$$

- decryption:

$$M = 11^{23} \bmod 187 = 88$$

# Exponentiation

- can use the Square and Multiply Algorithm
- a fast, efficient algorithm for exponentiation
- concept is based on repeatedly squaring base
- and multiplying in the ones that are needed to compute the result
- look at binary representation of exponent
- only takes  $O(\log_2 n)$  multiples for number  $n$ 
  - eg.  $7^5 = 7^4 \cdot 7^1 = 3 \cdot 7 = 10 \pmod{11}$
  - eg.  $3^{129} = 3^{128} \cdot 3^1 = 5 \cdot 3 = 4 \pmod{11}$

# Exponentiation

$c \leftarrow 0; d \leftarrow 1$

**for**  $i \leftarrow k$  **downto** 0

**do**  $c \leftarrow 2 \times c$

$d \leftarrow (d \times d) \bmod n$

**if**  $b_i = 1$

**then**  $c \leftarrow c + 1$

$d \leftarrow (d \times a) \bmod n$

**return**  $d$

# RSA Key Generation

- users of RSA must:
  - determine two primes at random -  $p, q$
  - select either  $e$  or  $d$  and compute the other
- primes  $p, q$  must not be easily derived from modulus  $N=p \cdot q$ 
  - means must be sufficiently large
  - typically guess and use probabilistic test
- exponents  $e, d$  are inverses, so use Inverse algorithm to compute the other

# RSA Security

- three approaches to attacking RSA:
  - brute force key search (infeasible given size of numbers)
  - mathematical attacks (based on difficulty of computing  $\phi(N)$ , by factoring modulus  $N$ )
  - timing attacks (on running of decryption)

# Factoring Problem

- mathematical approach takes 3 forms:
  - factor  $N=p \cdot q$ , hence find  $\phi(N)$  and then  $d$
  - determine  $\phi(N)$  directly and find  $d$
  - find  $d$  directly
- currently believe all equivalent to factoring
  - have seen slow improvements over the years
    - as of Aug-99 best is 130 decimal digits (512) bit with GNFS
  - biggest improvement comes from improved algorithm
    - cf “Quadratic Sieve” to “Generalized Number Field Sieve”
  - barring dramatic breakthrough 1024+ bit RSA secure
    - ensure  $p, q$  of similar size and matching other constraints

# Timing Attacks

- developed in mid-1990's
- exploit timing variations in operations
  - eg. multiplying by small vs large number
  - or IF's varying which instructions executed
- infer operand size based on time taken
- RSA exploits time taken in exponentiation
- countermeasures
  - use constant exponentiation time
  - add random delays
  - blind values used in calculations

# Summary

- have considered:
  - principles of public-key cryptography
  - RSA algorithm, implementation, security
